We said earlier that differentiable functions can be locally well-approximated by affine functions.

Loosely, f is differentiable $\rightarrow f(\vec{a} + \vec{h}) \approx f(\vec{a}) + D_f(\vec{a})(\vec{h})$ for $\vec{h} \approx 0$.
$$f(\vec{x}) \approx f(\vec{a}) + D_f(\vec{a})(\vec{x} - \vec{a}).$$

Suppose we also have $f(\vec{a}) : B \rightarrow Z$, where B is an open subset of W and Z is a normed vector space. With $\vec{b} \in B$, $g(\vec{y}) \approx g(\vec{b}) + D_g(\vec{b})(\vec{y} - \vec{b})$.

Combine $g(f(\vec{x})) \approx g(\vec{b}) + D_g(\vec{b})(f(\vec{x}) - f(\vec{a}))$
$$\approx g(\vec{b}) + D_g(\vec{b})D_f(\vec{a})(\vec{x} - \vec{a})$$
$$\approx g(f(\vec{a})) + (D_g(\vec{b}) \circ D_f(\vec{a}))(\vec{x} - \vec{a}).$$

This suggests $D_{(g \circ f)}(\vec{a}) = D_g(\vec{b}) \circ D_f(\vec{a})$.

This is the multivariable calculus chain rule.
